Regression models are used to describe relationships between variables by fitting a line to the observed data. Regression allows you to estimate how a dependent variable changes as the independent variable(s) change. Multiple linear regression is used to estimate the relationship between two or more independent variables and one dependent variable. You can use multiple linear regression when you want to know:

Multiple Linear Regression | A Quick and Simple Guide

Multiple regression is a commonly used analytic method in the behavioral, educational, and social sciences because it provides a way to model a quantitative outcome variable from regressor variables.1 Multiple regression is an especially important statistical model to understand because special cases and generalizations of multiple regression are many of the most commonly used models in empirical research.

Multiple regression is an extension of simple linear regression. It is used when we want to predict the value of a variable based on the value of two or more other variables. The variable we want to predict is called the dependent variable (or sometimes, the outcome, target or criterion variable).

Here is how to interpret each of the numbers in this section: Multiple R. This is the correlation coefficient. It measures the strength of the linear relationship between the predictor variables and the response variable. A multiple R of 1 indicates a perfect linear relationship while a multiple R of 0 indicates no linear relationship whatsoever.

Interpreting the Coefficient of a Categorical Predictor Variable. For a categorical predictor variable, the regression coefficient represents the difference in the predicted value of the response variable between the category for which the predictor variable = 0 and the category for which the predictor variable = 1.

For multiple linear regression, the interpretation remains the same. Use Polynomial Terms to Model Curvature in Linear Models. The previous linear relationship is relatively straightforward to understand. A linear relationship indicates that the change remains the same throughout the regression line.

A regression with two or more predictor variables is called a multiple regression. (When we need to note the difference, a regression on a single predic- tor is called a simple regression.) We'd never try to find a regression by hand, and even calculators aren't really up to the task. This is a job for a statistics program on a computer.
